Exploring word-frequency differences
in corpora

Tanja Säily & Jukka Suomela

UNIVERSITY OF HELSINKI

Aalto University

Comparing word frequencies

- Corpus linguists do this all the time
- **Significance** of differences observed?
 - **Bag-of-words** tests (e.g. chi-square, log-likelihood ratio test) assume words occur randomly in texts, overestimate significance
 - Tests based on **resampling**: assumption-free, yield confidence intervals
- *types2: permutation testing* (resampling)

Exploring word frequencies

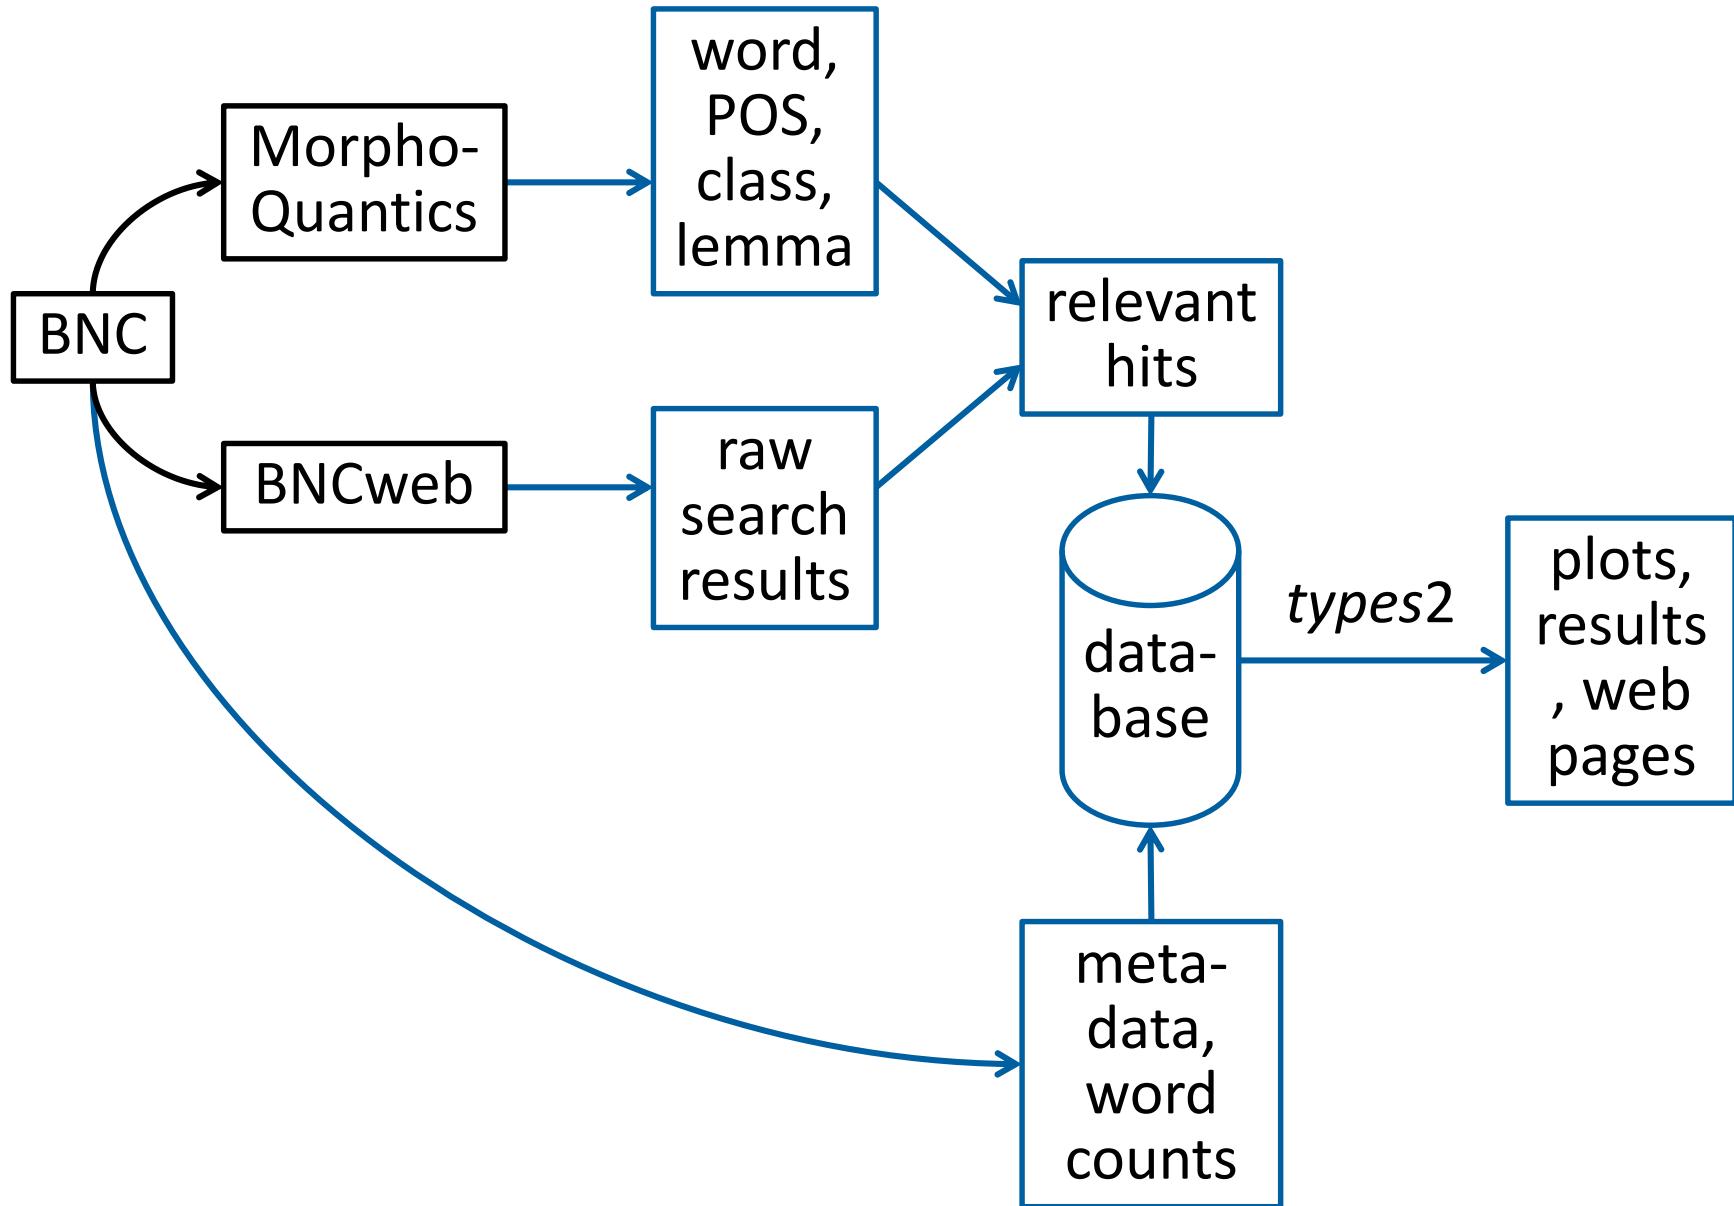

- Typically: static tables, figures
 - Not conducive to rapid exploration
- **Interpretation** of results?
 - Need to go back to the concordances & metadata
- *types2*: online interface with interactive figures, **linked data**

How does it work?

- Do a corpus search
 - BNCweb, WordSmith Tools...
- Narrow down to relevant hits
- **Input** for *types2*: relevant hits + corpus metadata
- **Output**: plots, results, web pages...

Example: Productivity in the BNC

- Derivational suffixes: *-er, -or*
 - **Sociolinguistic variation** in their productivity?
 - Productivity ~ type frequency
- BNC = British National Corpus
 - Demographically sampled spoken component,
both gender & social class known: 2.6 Mw
 - **BNCweb** (Lancaster University)
 - **MorphoQuantics** (Laws & Ryder 2014)

This collection contains 1582116 running words and 417 types.

Only approx. **0.001%** of random collections with 1582116 running words contain at most 417 types.

This finding is probably interesting: the false discovery rate is **smaller than 0.01**.

This collection contains 583086 running words and 133 types.

Only approx. **0.000%** of random collections with 583086 running words contain at most 133 types.

This finding is probably interesting: the false discovery rate is **smaller than 0.001**.
